## ABSTRACT

Robust Linear Regression is the problem of fitting data to a distribution,  $\mathbb{P}$  when there exists contaminated samples,  $\mathbb{Q}$ . We model this as  $\hat{\mathbb{P}} = (1 - \varepsilon)\mathbb{P} + \varepsilon\mathbb{Q}$ . Traditional Least Squares Methods fit the empirical risk model to all training data in  $\hat{\mathbb{P}}$ . In this paper we show theoretical and experimental results of sub-quantile optimization, where we optimize with respect to the  $p$ -quantile of the empirical loss.

## 1 INTRODUCTION

Linear Regression is one of the most widely used statistical estimators throughout Science. Although robustness is only a somewhat recent topic in machine learning, it has been a topic in statistics for many decades. Several popular methods have been very popular due to their simplicity and high effectiveness including quantile regression Koenker & Hallock (2001), Theil-Sen Estimator Sen (1968), and Huber Regression Huber & Ronchetti (2009).

Our goal is to provide a theoretic analysis and convergence conditions for sub-quantile optimization and offer practioners a method for robust linear regression.

Sub-Quantile Optimization aims to address the shortcomings of ERM in applications such as noisy/corrupted data (Khetan et al. (2018), Jiang et al. (2018)), classification with imbalanced classes, (Lin et al. (2017), He & Garcia (2009)), as well as fair learning (Corbett-Davies & Goel (2018)).

## 2 RELATED WORK

Least Trimmed Squares (LTS) Mount et al. (2014).

\*Work done as a part of ML and Optimization Spring 2023 Group Project.

Tilted Empirical Risk Minimization (TERM) Li et al. (2020) is a framework built to similarly handle the shortcomings of ERM with respect to robustness. The TERM framework instead minimizes the following quantity, where  $t$  is a hyperparameter

$$\tilde{R}(t; \boldsymbol{\theta}) := \frac{1}{t} \log \left( \frac{1}{N} \sum_{i \in [N]} e^{tf(\mathbf{x}_i; \boldsymbol{\theta})} \right) \quad (1)$$

SMART Awasthi et al. (2022) proposes the *iterative trimmed maximum likelihood estimator* against adversarially corrupted samples in General Linear Models (GLM). The estimator is defined as follows, where  $S = \{(\mathbf{x}_i, y_i)\}_{i=1}^n$  represents the training data.

$$\hat{\boldsymbol{\theta}}(S) = \min_{\boldsymbol{\theta}} \min_{\hat{S} \subset S, |\hat{S}|=(1-\epsilon)n} \sum_{(\mathbf{x}_i, y_i) \in \hat{S}} -\log f(y_i | \boldsymbol{\theta}^\top \mathbf{x}_i) \quad (2)$$

SEVER Diakonikolas et al. (2019) is a gradient filtering algorithm which removes elements whose gradients have the furthest distance from the average gradient of all points

$$\tau_i = \left( (\nabla f_i(\mathbf{w}) - \hat{\nabla}) \cdot \mathbf{v} \right)^2 \quad (3)$$

### 3 SUB-QUANTILE OPTIMIZATION

**Definition 1.** Let  $F_X$  represent the Cumulative Distribution Function (CDF) of the random variable  $X$ . The **p-Quantile** of a Random Variable  $X$  is defined as follows

$$Q_p(p) = \inf\{x \in \mathbb{R} : p \leq F(x)\} \quad (4)$$

Note  $Q_p(0.5)$  represents the median of the random variable.

**Definition 2.** The **Empirical Distribution Function** is defined as follows

$$\hat{F}_n(t) = \frac{1}{n} \sum_{i=1}^n \mathbb{1}_{X_i \leq t} \quad (5)$$

**Definition 3.** Let  $\ell$  be the loss function. **Risk** is defined as follows

$$U = \mathbb{E}[\ell(f(\mathbf{x}; \boldsymbol{\theta}), \mathbf{y})] \quad (6)$$

The **p-Quantile** of the Empirical Risk is given

$$\mathbb{L}_p(U) = \frac{1}{p} \int_0^p Q_q(U) dq = \mathbb{E}[U | U \leq Q_p(U)] = \max_{t \in \mathbb{R}} \left\{ t - \frac{1}{p} \mathbb{E}[(t - U)^+] \right\} \quad (7)$$

In equation 7,  $t$  represents the  $p$ -quantile of  $U$ . We also show that we can calculate  $t$  by a maximizing optimization function. The Sub-Quantile Optimization problem is posed as follows

$$\boldsymbol{\theta}_{SM} = \arg \min_{\boldsymbol{\theta} \in \mathbb{R}^d} \max_{t \in \mathbb{R}} \left\{ t - \frac{1}{p} \mathbb{E}(t - \ell(f(\mathbf{x}; \boldsymbol{\theta}), \mathbf{y}))^+ \right\} \quad (8)$$

For the linear regression case, this equation becomes

$$\boldsymbol{\theta}_{SM} = \arg \min_{\boldsymbol{\theta} \in \mathbb{R}^d} \max_{t \in \mathbb{R}} \left\{ t - \frac{1}{np} \sum_{i=1}^n (t - (\boldsymbol{\theta}^\top \mathbf{x}_i - y_i)^2)^+ \right\} \quad (9)$$

The two-step optimization for Sub-Quantile optimization is given as follows

$$t_{k+1} = \arg \max_t g(t, \boldsymbol{\theta}_k) \quad (10)$$

$$\boldsymbol{\theta}_{k+1} = \boldsymbol{\theta}_k + \alpha \nabla_{\boldsymbol{\theta}_k} g(t, \boldsymbol{\theta}_k) \quad (11)$$

This algorithm is adopted from Razaviyayn et al. (2020). Theoretically, it has been proven to converge in research by Jin et al. (2019).

### 3.1 MOTIVATION

**Assumption 1.** *To provide theoretical bounds on the effectiveness of Sub-Quantile Minimization, we make the General Linear Model Assumption that*

$$\mathbf{y}_P = \mathbf{P}\beta_P + \epsilon_P \quad (12)$$

and similarly

$$\mathbf{y}_Q = \mathbf{Q}\beta_Q + \epsilon_Q \quad (13)$$

where  $\beta_P$  and  $\beta_Q$  the oracle regressors for  $\mathbb{P}$  and  $\mathbb{Q}$  and  $\epsilon_P$  and  $\epsilon_Q$  are both Normally Distributed with mean 0.

Since we are interested in learning the optimal model for distributions, our goal is to learn the parameters  $\beta_P$  from the distribution  $\hat{\mathbb{P}}$ . We want to clarify the corruption is not adversarially chosen. In this section we quantify the effect of corruption on the desired model. To introduce notation, let  $\mathbf{P}$  represent the data from distribution  $\mathbb{P}$  and let  $\mathbf{Q}$  represent the training data for  $\mathbb{Q}$ . Let  $\mathbf{y}_P$  represent the target data for  $\mathbb{P}$  and let  $\mathbf{y}_Q$  represent the target data for  $\mathbb{Q}$ .

**Assumption 2.** *We assume the rows of  $\mathbf{P}$  and  $\mathbf{Q}$  are sampled from the same multivariate normal distribution.*

$$\mathbf{P}_i, \mathbf{Q}_j \sim \mathcal{N}_p(\mathbf{0}, \Sigma) \quad (14)$$

We will use our assumptions to quantify the effect of the corrupted data on an optimal least squares regression model. We are interested in  $(\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{y} - (\mathbf{P}^\top \mathbf{P})^{-1} \mathbf{P}^\top \mathbf{y}$ . It is known the least squares optimal solution for  $\mathbf{X}$  is equal to  $(\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{y}$

Note  $\mathbf{X} = \begin{pmatrix} \mathbf{P} \\ \mathbf{Q} \end{pmatrix}$  and  $\mathbf{y} = \begin{pmatrix} \mathbf{y}_P \\ \mathbf{y}_Q \end{pmatrix}$  so  $\mathbf{X}^\top = (\mathbf{P}^\top \quad \mathbf{Q}^\top)$

**Theorem 1.** *The expected optimal parameters of the corrupted model  $\hat{\mathbb{P}}$*

$$\mathbb{E}[\mathbf{X}^\dagger \mathbf{y}] = \beta_P + \epsilon(\beta_Q - \beta_P) \quad (15)$$

The proof is reliant on assumption 2, this allows us to utilize the Wishart Distribution,  $\mathcal{W}$ , and the inverse Wishart Distribution,  $\mathcal{W}^{-1}$ . Please refer to Appendix B.1. By Theorem 1 we can see the level of corruption is dependent upon  $\epsilon$ , which represents the percentage of corrupted samples, and the distance between the optimal parameters for  $\mathbb{P}$ , which is  $\beta_P$  and the optimal parameters for  $\mathbb{Q}$ , which is  $\beta_Q$ .

Here we utilize the idea of *influence* from McWilliams et al. (2014).

Theorem 1 finds the optimal model when the corrupted distribution is sampled from the same distribution as the target distribution but has different optimal parameters. We will now look at the case of feature corruption. This is where the optimal parameters of the two distributions are the same but the data from  $\mathbb{P}$  and  $\mathbb{Q}$  are sampled differently.

**Theorem 2.** *In the case of  $\mathbb{P}$  and  $\mathbb{Q}$  being from different Normal Distributions. The expected optimal parameters of the corrupted model  $\hat{\mathbb{P}}$*

$$\mathbb{E}[\mathbf{X}^\dagger \mathbf{y}] = \beta_P - n(1 - \epsilon)\Sigma_P^{-1}\beta_P \quad (16)$$

The proof can be found in Appendix B.2. We will show our results hold in Numerical Experiments. As seen in the results in table 1, the theory we provide is supported by Numerical Experimentation.

In equation 15, note as  $\epsilon \rightarrow 0$  we are returned  $\beta_P$ . This is the intuition behind SubQuantile Minimization. By minimizing over the SubQuantile, we seek to reduce  $\epsilon$ , and thus our model will return a model which is by expectation closer to  $\beta_P$ .

## 4 THEORY

### 4.1 ANALYSIS OF $g(t, \theta)$

In this section, we will explore the fundamental aspects of  $g(t, \theta)$ . This will motivate the convergence analysis in the next section.

**Lemma 4.1.**  $g(t_{k+1}, \theta_k)$  is concave with respect to  $t$ .

*Proof.* We provide a simple argument for concavity. Note  $t$  is a concave and convex function. Also  $(\cdot)^+$  is a convex strictly non-negative function. Therefore we have a concave function minus the non-negative multiple of a summation of an affine function composed with a convex function. Therefore this is a concave function with respect to  $t$ .  $\square$

**Lemma 4.2.** The maximizing value of  $t$  in  $g(t, \theta)$  in  $t$ -update step of optimization as described by Equation 10 is maximized when  $t = Q_p(U)$

*Proof.* Since  $g(t, \theta)$  with respect to  $t$  is a concave function. Maximizing  $g(t, \theta)$  is equivalent to minimizing  $-g(t, \theta)$ . We will find fermat’s optimality condition for the function  $-g(t, \theta)$ , which is convex. Let  $\hat{\nu} = \text{sorted}((\theta^\top \mathbf{X} - \mathbf{y})^2)$  and note  $0 < p < 1$

$$\partial(-g(t, \theta)) = -1 + \frac{1}{np} \sum_{i=1}^n \begin{cases} 1, & \text{if } t > \hat{\nu}_i \\ 0, & \text{if } t < \hat{\nu}_i \\ [0, 1], & \text{if } t = \hat{\nu}_i \end{cases} \quad (17)$$

$$= 0 \text{ when } t = \hat{\nu}_{np} \quad (18)$$

This is the  $p$ -quantile of  $U$ . A full proof is provided in Appendix C.1.  $\square$

**Lemma 4.3.** Let  $t = \hat{\nu}_{np}$ . The  $\theta$ -update step described in Equation 9 is equivalent to minimizing the least squares loss of the  $np$  elements with the lowest squared loss.

$$\nabla_{\theta} g(t_{k+1}, \theta_k) = \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i(\theta_k^\top \mathbf{x}_i - y_i) \quad (19)$$

We provide a proof in Appendix C.2. However, this result is quite intuitive as it shows we are optimizing over the  $p$  Sub-Quantile of the Risk.

**Interpretation 1.** Sub-Quantile Minimization continuously minimizes the risk over the  $p$ -quantile of the error. In each iteration, this means we reduce the error of the points within the lowest  $np$  errors.

**Lemma 4.4.**  $g(t_{k+1}, \theta_k)$  is convex with respect to  $\theta_k$ .

*Proof.* We see by lemma 4.2 and interpretation 1, we are optimizing by the  $np$  points with the lowest squared error. Mathematically,

$$g(t_{k+1}, \theta_k) = t_{k+1} - \frac{1}{np} \sum_{i=1}^n (t_{k+1} - (\theta^\top \mathbf{x}_i - y_i)^2)^+ \quad (20)$$

$$= t_{k+1} - \frac{1}{np} \sum_{i=1}^{np} (t_{k+1} - (\theta^\top \mathbf{x}_i - y_i)^2)^+ \quad (21)$$

$$= t - t + \frac{1}{np} \sum_{i=1}^{np} (\theta^\top \mathbf{x}_i - y_i)^2 \quad (22)$$

$$= \frac{1}{np} \sum_{i=1}^{np} (\theta^\top \mathbf{x}_i - y_i)^2 \quad (23)$$

Now we can make a simple argument for convexity. We have a non-negative multiple of the sum of the composition of an affine function with a convex function. Thus  $g(t, \theta)$  is convex with respect to  $\theta$ .  $\square$

**Lemma 4.5.**  $g(t, \theta)$  is  $L$ -smooth with respect to  $\theta$  with  $L = \left\| \frac{2}{np} \sum_{i=1}^{np} \|\mathbf{x}_i\|^2 \right\|$

#### 4.2 OPTIMIZATION

We are solving a min-max convex-concave problem, thus we are looking for a Nash Equilibrium Point.

**Definition 4.**  $(t^*, \theta^*)$  is a *Nash Equilibrium* of  $g$  if for any  $(t, \theta) \in \mathbb{R} \times \mathbb{R}^d$

$$g(t^*, \theta) \leq g(t^*, \theta^*) \leq g(t, \theta^*) \quad (24)$$

**Definition 5.**  $(t^*, \theta^*)$  is a *Local Nash Equilibrium* of  $g$  if there exists  $\delta > 0$  such that for any  $t, \theta$   $(t, \theta)$  satisfying  $\|t - t^*\| \leq \delta$  and  $\|\theta - \theta^*\| \leq \delta$  then:

$$g(t^*, \theta) \leq g(t^*, \theta^*) \leq g(t, \theta^*) \quad (25)$$

**Proposition 1.** As  $g$  is first-order differentiable, any local Nash Equilibrium satisfies  $\nabla_\theta g(t, \theta) = 0$  and  $\nabla_t g(t, \theta) = 0$

We are now interested in what it means to be at a Local Nash Equilibrium. By Proposition 1, this means both first-order partial derivatives are equal to 0. By lemma 4.2, we have shown  $\nabla_t g(t, \theta) = 0$  when  $\nu_{np} \leq t < \nu_{np+1}$ . Furthermore, by lemma 4.3, we have shown  $\nabla_\theta(g, \theta) = 0$  when the least squares error is minimized for the  $np$  points with lowest squared error. This means that for a subset of  $np$  points from  $\mathbf{X}$ , the least squares error is minimized. What we are interested in is how many points within those  $np$  points come from  $\mathbb{P}$  and how many of those points from  $\mathbb{Q}$ . Our goal is to minimize the number of points within the  $np$  lowest squared losses from  $\mathbb{Q}$ , as they will introduce error to our predictions on points from  $\mathbb{P}$ .

**Lemma 4.6.** If  $t_{k+1} \leq t_k$  then  $g(t_{k+1}, \theta_k) = g(t_k) + \frac{1}{np} \sum_{i=np}^n (t_k - \nu_i)^+$ . If  $t_{k+1} > t_k$ , then  $g(t_{k+1}, \theta_k) = g(t_k) + \frac{1}{np} \sum_{i=n(p-\delta)}^{np} (t - \nu_i)^+ - \delta t$ . For a small  $\delta$ . *This is just a general property, unsure if worth keeping.*

*Proof Sketch.* When  $t_{k+1} \leq t_k$  this result is quite intuitive, as we are simply removing the error of the elements outside elements within the lowest  $np$  squared losses. We delegate the rest of the proof to Appendix E.1  $\square$

#### 4.3 CONVERGING TO $\beta_P$

We will start by defining the two types of noise we are interesting in.

**Definition 6.** *Unstructured Noise* is noise that is not dependent on the input data, i.e.,  $\mathbb{P}[\mathbf{y}|\mathbf{X}] = \mathbb{P}[\mathbf{X}]$

**Definition 7.** *Linearly Structured Noise* is noise that is made from a linear combination of the input data, i.e.  $\mathbf{y} = \beta_Q \mathbf{X} + \epsilon$

Also note we often consider Gaussian Noise as Unstructured Noise, but it can be modeled as Structured Noise where  $\beta_Q = \mathbf{0}$ .

**Theorem 3.** *The Expected Value of Epsilon can be calculated as:*

$$\mathbb{E}[\epsilon] = \frac{\mathbb{E}[P^+]}{np} \quad (26)$$

We provide a proof in Appendix F.1. Furthermore, we validate our theoretical estimation of the number of elements of  $\mathbb{P}$  less than  $Q_p$  as well as our estimation of  $Q_p$  in figures ... & .... Our strongest theoretical results for convergence come in the case of *Linearly Structured Noise*.

**Theorem 4.** *The convergence of SubQuantile Optimization is dependent on the initial weights  $\theta_0$  in the case of linearly structured noise.*

*Proof Sketch.* Let us consider a worst-case scenario where  $\theta_k = \beta_Q$ . Note this is not an impossible situation as if you naively choose  $\theta_0 = \mathbf{0}$  and  $\mathbb{Q} \sim \mathcal{N}(\mathbf{0}, \Sigma_Q)$ .  $\square$

Theorem 4 tells us we can not randomly select weights and expect to converge to the majority class. We must choose the initial weights in a specific way as such so we can guarantee the majority elements by expectation have more representation within the lowest  $np$  squared losses after the loss iteration.

**Theorem 5.** *If we choose  $\theta_0 = (\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{y}$  then SubQuantile optimization converges almost surely. Fairly confident this is not true, even in the linearly structured noise case.*

*Proof Sketch.* By Theorem 1,  $\theta_0 = (1 - \epsilon)\beta_P + \epsilon\beta_Q$   $\square$

We are now interested in theoretical guarantees with no distributional assumptions. First we will consider some intuition on why this problem is not as hard as compared to when the corruption is linearly structured. Let us say the noise is of non-linear regression, in other words  $\mathbf{y}_Q \sim f(\mathbf{X}, \beta_Q)$ , where  $f$  is a non-linear combination of features of  $\mathbf{X}$ . In this case, it is not possible to model the non-linear regression by a linear combination of the features, thus, if we have elements from  $\mathbb{Q}$  within the lowest  $np$  losses, then training on these points will not generalize well to points from  $\mathbb{Q}$ , so their error will not decrease.

## 5 EMPIRICAL RESULTS

The first experiment we will run will display the difference of the following two  $t$  updates

$$t_{k+1} = \hat{\nu}_{np} \quad (27)$$

$$t_{k+1} = \frac{1}{np} \sum_{i=1}^{np} \hat{\nu}_i \quad (28)$$

In general, if the  $\hat{\nu}_1, \hat{\nu}_2, \dots, \hat{\nu}_{np}$  are closely distributed, then  $\frac{1}{np} \sum_{i=1}^{np} \hat{\nu}_i \approx \hat{\nu}_{np}$ . In Algorithm 1, we display our training method for Sub-quantile Optimization with the  $t$  update as described in equation 27. We also compare against the  $t$ -update as described in equation 28.

**Algorithm 1:** Sub-Quantile Minimization Optimization Algorithm

---

**Input:** Training iterations  $T$ , Quantile  $p$ , Corruption Percentage  $\epsilon$ , Input Parameters  $m$   
**Output:** Trained Parameters,  $\theta$   
**Data:** Inliers:  $y|x \sim \mathcal{N}(x^2 - x + 2, 0.01)$ , Outliers:  $y|x \sim \mathcal{N}(-x^2 + x + 4, 0.01)$

```

1:  $\theta_0 \leftarrow \frac{2}{L} \sum_{i=1}^n (x_i y_i)$ 
2: for  $k \in 1, 2, \dots, m$  do
3:    $\nu = (X\theta_k - y)^2$ 
4:    $\hat{\nu} = \text{sorted}(\nu)$ 
5:    $t_{k+1} = \hat{\nu}_{np}$ 
6:    $t_{k+1} = \frac{1}{np} \sum_{i=1}^{np} \nu_i$ 
7:    $L := \sum_{i=1}^{np} x_i^\top x_i$ 
8:    $\alpha := \frac{1}{2L}$ 
9:    $\theta_{k+1} = \theta_k - \alpha \nabla_{\theta_k} g(t_{k+1}, \theta_k)$ 
10: end
11: if  $\epsilon > 0.5$  then
12:    $P = \hat{\nu} [np : ]$ 
13:    $y_P = y [np : ]$ 
14:    $\theta_T = (P^\top P)^{-1} P^\top y_P$ 
15: end
16: return  $\theta_T$ 

```

---

We also present a batch algorithm which improves training speed significantly. In accordance with Minibatch theory, if the subset  $I$  of all data is representative of all the data, then this will have similar results to Algorithm 1.

### 5.1 SYNTHETIC DATA

We now demonstrate SubQuantile Regression in the presence of Gaussian Random Noise.

From the results we can see in Figure ??, Subquantile Minimization performs better throughout all noise ranges. The one struggle exists when  $\epsilon$  is around 0.5, thus we face issues similar to the power method where there exists the top two eigenvalues such that  $|\lambda_1| \approx |\lambda_2|$ .

In our first synthetic experiment, we run Algorithm 1 on synthetically generated structured linear regression data, the noise is sampled from a linear distribution that is dependent on the vector of  $\mathbf{X}$ . The results of Sub-Quantile Minimization can be seen in Figure 1. Our results show the near optimal performance of Sub-Quantile Minimization. The results and comparison with other methods can be seen in Table 2. Note we are not interested in  $\epsilon \geq 0.5$  as the concept of corruptness becomes unclear. We see in Table 2, Sub-Quantile Minimization produces State of the Art Results in the Quadratic Regression Case. Furthermore, it performs significantly better than baseline methods in the high-noise regimes ( $\epsilon = 0.4$ ), this is confirmed in both the small data and large data datasets. Please refer to Appendix H for more details on the Structured Linear Regression Dataset.

In our second synthetic experiment, we run Algorithm 1 similarly on synthetically generated linear regression data. However, in this experiment, the noise is sampled from a Gaussian that is independent of the  $\mathbf{X}$  coordinates.

Methods such as TERM, Li et al. (2020), are unable to capture the target distribution through structurally generated noise, which can also be called *adversarial*. SubQuantile Optimization, on the other hand, is robust to such adversarial attacks.

### 5.2 REAL DATA

We provide results on the Drug Discovery Dataset in Diakonikolas et al. (2019) utilizing the noise procedure described in Li et al. (2020).

As we can see in Table 3, we obtain state of the art results in the lower range of range of noise, and further more, we obtain results on par with the current state of the art. This makes our model the

## 6 CONCLUSION

In this work we provide a theoretical analysis for robust linear regression by minimizing the *Sub-Quantile* of the Empirical Risk. Furthermore, we run various numerical experiments and compare against the current State of the Art in Robust Linear Regression.

## A ASSUMPTIONS

## B PROOFS IN SECTION 3

### B.1 PROOF OF THEOREM 1

*Proof.*

We will first calculate the pseudo-inverse

$$\mathbf{X}^\top \mathbf{X} = (\mathbf{P}^\top \quad \mathbf{Q}^\top) \begin{pmatrix} \mathbf{P} \\ \mathbf{Q} \end{pmatrix} \quad (29)$$

$$= \mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q} \quad (30)$$

Now we can calculate the Moore-Penrose Inverse

$$(\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top = (\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} (\mathbf{P}^\top \quad \mathbf{Q}^\top) \quad (31)$$

$$= ((\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \mathbf{P}^\top \quad (\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \mathbf{Q}^\top) \quad (32)$$

Now we solve for the optimal model

$$\mathbf{X}^\dagger \mathbf{y} = ((\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \mathbf{P}^\top \quad (\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \mathbf{Q}^\top) \begin{pmatrix} \mathbf{y}_P \\ \mathbf{y}_Q \end{pmatrix} \quad (33)$$

$$= (\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \mathbf{P}^\top \mathbf{y}_P + (\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \mathbf{Q}^\top \mathbf{y}_Q \quad (34)$$

By assumption 2, all rows of  $\mathbf{P}$  and  $\mathbf{Q}$  are sampled from a common Normal Distribution. Thus we are able to utilize properties of the Wishart Distribution, Nydick (2012).

$$\mathbf{P}^\top \mathbf{P} = \sum_{\substack{i=1 \\ n \in}}^{n*(1-\epsilon)} \mathbf{P}_i \mathbf{P}_i^\top \quad (35)$$

$$\mathbf{Q}^\top \mathbf{Q} = \sum_{j=1}^{n\epsilon} \mathbf{Q}_j \mathbf{Q}_j^\top \quad (36)$$

Thus we can say  $\mathbf{P}^\top \mathbf{P}$  and  $\mathbf{Q}^\top \mathbf{Q}$  are sampled from the Wishart distribution.

$$\mathbf{P}^\top \mathbf{P} \sim \mathcal{W}(n(1-\epsilon), \Sigma) \quad (37)$$

$$\mathbf{Q}^\top \mathbf{Q} \sim \mathcal{W}(n\epsilon, \Sigma) \quad (38)$$

We can now use the Expected Value of the Wishart Distribution.

$$\mathbb{E}(\mathbf{P}^\top \mathbf{P}) = n(1-\epsilon)\Sigma \quad (39)$$

$$\mathbb{E}(\mathbf{Q}^\top \mathbf{Q}) = n\epsilon\Sigma \quad (40)$$

It thus follows

$$\mathbb{E}[\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q}] = n\Sigma \quad (41)$$

Since we are interested in the pseudo-inverse, we will utilize the Inverse Wishart Distribution.

$$(\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1} \sim \mathcal{W}^{-1}(n, \Sigma) \quad (42)$$

It thus follows by the expectation of the Inverse Wishart Distribution

$$\mathbb{E}[(\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1}] = n\Sigma^{-1} \quad (43)$$

Now we will plug this into Equation 34:

$$\mathbb{E}[\mathbf{X}^\dagger \mathbf{y}] = (n\Sigma^{-1}) \mathbf{P}^\top \mathbf{y}_P + (n\Sigma^{-1}) \mathbf{Q}^\top \mathbf{y}_Q \quad (44)$$

$$= (n\Sigma^{-1}) \mathbf{P}^\top (\mathbf{P}\beta + \epsilon_P) + (n\Sigma^{-1}) \mathbf{Q}^\top (\mathbf{Q}\beta_Q + \epsilon_Q) \quad (45)$$

$$= (n\Sigma^{-1}) ((\mathbf{P}^\top \mathbf{P})\beta_P + (\mathbf{Q}^\top \mathbf{Q})(\beta_P + (\beta_Q - \beta_P))) \quad (46)$$

$$= (n\Sigma^{-1}) ((n(1-\epsilon)\Sigma)\beta_P + n\epsilon\Sigma(\beta_P + \Psi)) \quad (47)$$

$$= (n\Sigma^{-1}) (n\Sigma\beta_P + n\epsilon\Sigma\Psi) \quad (48)$$

$$= \beta_P + \epsilon(\Psi) \quad (49)$$

This concludes the proof.  $\square$

## B.2 PROOF OF THEOREM 2

*Proof.* The first half of the proof follows from Appendix B.1. We start by noting new notation.  $\Sigma_P$  represents the covariance matrix for  $\mathbb{P}$  and  $\Sigma_Q$  represents the covariance matrix for  $\mathbb{Q}$ .

$$\mathbb{E} [\mathbf{P}^\top \mathbf{P}] = n(1 - \epsilon) \Sigma_P \quad (50)$$

$$\mathbb{E} [\mathbf{Q}^\top \mathbf{Q}] = n\epsilon \Sigma_Q \quad (51)$$

It thus follows

$$\mathbb{E} [\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q}] = (n(1 - \epsilon) \Sigma_P + n\epsilon \Sigma_Q) \quad (52)$$

This is where the structure of the proof because we can no longer follow the Inverse Wishart Distribution.

$$\mathbb{E} [(\mathbf{P}^\top \mathbf{P} + \mathbf{Q}^\top \mathbf{Q})^{-1}] = (n(1 - \epsilon) \Sigma_P + n\epsilon \Sigma_Q)^{-1} \quad (53)$$

Now we can use the Woodbury Formula Golub & Van Loan (1996)

$$= n(1 - \epsilon) \Sigma_P^{-1} - n(1 - \epsilon) \Sigma_P^{-1} (n\epsilon \Sigma_Q^{-1}) \quad (54)$$

We will now calculate the expected optimal parameters by plugging this into Equation 34:

$$\mathbb{E} [\mathbf{X}^\dagger \mathbf{y}] = n(1 - \epsilon) \Sigma_P^{-1} (\mathbf{P}^\top \mathbf{P}) \beta_P - n(1 - \epsilon) \Sigma_P^{-1} (n\epsilon \Sigma_Q^{-1}) (\mathbf{Q}^\top \mathbf{Q}) \beta_P \quad (55)$$

$$= n(1 - \epsilon) \Sigma_P^{-1} (n(1 - \epsilon) \Sigma_P) \beta_P - n(1 - \epsilon) \Sigma_P^{-1} (n\epsilon \Sigma_Q^{-1}) (n\epsilon \Sigma_Q) \beta_P \quad (56)$$

$$= \beta_P - n(1 - \epsilon) \Sigma_P^{-1} \beta_P \quad (57)$$

This concludes the proof.  $\square$

## C GENERAL PROPERTIES OF SUB-QUANTILE MINIMIZATION

### C.1 PROOF OF LEMMA 4.2

*Proof.* Since  $g(t, \theta)$  is a concave function. Maximizing  $g(t, \theta)$  is equivalent to minimizing  $-g(t, \theta)$ . We will find fermat's optimality condition for the function  $-g(t, \theta)$ , which is convex. Let  $\hat{\nu} = \text{sorted}((\theta^\top \mathbf{X} - \mathbf{y})^2)$  and note  $0 < p < 1$

$$\partial(-g(t, \theta)) = \partial\left(-t + \frac{1}{np} \sum_{i=1}^n (t - \hat{\nu}_i)^+\right) \quad (58)$$

$$= \partial(-t) + \partial\left(\frac{1}{np} \sum_{i=1}^n (t - \hat{\nu}_i)^+\right) \quad (59)$$

$$= -1 + \frac{1}{np} \sum_{i=1}^n \partial(t - \hat{\nu}_i)^+ \quad (60)$$

$$= -1 + \frac{1}{np} \sum_{i=1}^n \begin{cases} 1, & \text{if } t > \hat{\nu}_i \\ 0, & \text{if } t < \hat{\nu}_i \\ [0, 1], & \text{if } t = \hat{\nu}_i \end{cases} \quad (61)$$

$$= 0 \text{ when } t = \hat{\nu}_{np} \quad (62)$$

This is the  $p$ -quantile of  $\nu$ . Not necessarily the  $p$ -quantile of  $Q_p(U)$   $\square$

### C.2 PROOF OF LEMMA 4.3

*Proof.* Note that  $t_k = \nu_{np}$  which is equivalent to  $(\theta_k^\top \mathbf{x}_{np} - y_{np})^2$

$$\nabla_{\theta_k} g(t_{k+1}, \theta_k) = \nabla_{\theta_k} \left( \nu_{np} - \frac{1}{np} \sum_{i=1}^n (\nu_{np} - (\theta_k^\top \mathbf{x}_i - y_i)^2)^+ \right) \quad (63)$$

$$= \nabla_{\theta_k} \left( (\theta_k^\top \mathbf{x}_{np} - y_{np})^2 - \frac{1}{np} \sum_{i=1}^n ((\theta_k^\top \mathbf{x}_{np} - y_{np})^2 - (\theta_k^\top \mathbf{x}_i - y_i)^2)^+ \right) \quad (64)$$

$$= \nabla_{\theta_k} (\theta_k^\top \mathbf{x}_{np} - y_{np})^2 - \frac{1}{np} \sum_{i=1}^n \nabla_{\theta_k} ((\theta_k^\top \mathbf{x}_{np} - y_{np})^2 - (\theta_k^\top \mathbf{x}_i - y_i)^2)^+ \quad (65)$$

$$= 2\mathbf{x}_{np}(\theta_k^\top \mathbf{x}_{np} - y_{np}) - \frac{1}{np} \sum_{i=1}^n 2\mathbf{x}_{np}(\theta_k^\top \mathbf{x}_{np} - y_{np}) - 2\mathbf{x}_i(\theta_k^\top \mathbf{x}_i - y_i) \begin{cases} 1, & \text{if } t > v_i \\ 0, & \text{if } t < v_i \\ [0, 1], & \text{if } t = v_i \end{cases} \quad (66)$$

$$= 2\mathbf{x}_{np}(\theta_k^\top \mathbf{x}_{np} - y_{np}) - \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_{np}(\theta_k^\top \mathbf{x}_{np} - y_{np}) - 2\mathbf{x}_i(\theta_k^\top \mathbf{x}_i - y_i) \quad (67)$$

$$= 2\mathbf{x}_{np}(\theta_k^\top \mathbf{x}_{np} - y_{np}) - 2\mathbf{x}_{np}(\theta_k^\top \mathbf{x}_{np} - y_{np}) + \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i(\theta_k^\top \mathbf{x}_i - y_i) \quad (68)$$

$$= \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i(\theta_k^\top \mathbf{x}_i - y_i) \quad (69)$$

This is the derivative of the  $np$  samples with lowest error with respect to  $\theta$ .  $\square$

## C.3 PROOF OF LEMMA 4.5

The objective function  $g(\boldsymbol{\theta}, t)$  is  $L$ -smooth w.r.t  $\boldsymbol{\theta}$  iff

$$\|\nabla_{\boldsymbol{\theta}} g(\boldsymbol{\theta}', t) - \nabla_{\boldsymbol{\theta}} g(\boldsymbol{\theta}, t)\| \leq L \|\boldsymbol{\theta}' - \boldsymbol{\theta}\| \quad (70)$$

$$\left\| \nabla_{\boldsymbol{\theta}} g(\boldsymbol{\theta}', t) - \nabla_{\boldsymbol{\theta}} g(\boldsymbol{\theta}, t) \right\| = \left\| \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i(\boldsymbol{\theta}'^T \mathbf{x}_i - y_i) - \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i(\boldsymbol{\theta}^T \mathbf{x}_i - y_i) \right\| \quad (71)$$

$$= \left\| \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i(\boldsymbol{\theta}'^T \mathbf{x}_i - \boldsymbol{\theta}^T \mathbf{x}_i) \right\| \quad (72)$$

$$= \left\| \frac{1}{np} \sum_{i=1}^{np} 2\mathbf{x}_i^T \mathbf{x}_i (\boldsymbol{\theta}'^T - \boldsymbol{\theta}^T) \right\| \quad (73)$$

$$\stackrel{\text{Cauchy-Schwarz}}{\leq} \left\| \frac{2}{np} \sum_{i=1}^{np} \|\mathbf{x}_i\|^2 \right\| \left\| \boldsymbol{\theta}'^T - \boldsymbol{\theta}^T \right\| \quad (74)$$

$$= L \left\| \boldsymbol{\theta}'^T - \boldsymbol{\theta}^T \right\| \quad (75)$$

where  $L = \left\| \frac{2}{np} \sum_{i=1}^{np} \|\mathbf{x}_i\|^2 \right\|$

This concludes the proof.

## D STOCHASTIC SUB-QUANTILE OPTIMIZATION

In the age of big data, stochastic methods are necessary for fast training of models to handle large amounts of data. In this section we will provide an algorithm for Stochastic Sub-Quantile Optimization and [prove convergence](#).

---

### Algorithm 2: Stochastic Sub-Quantile Minimization Optimization Algorithm

---

**Input:** Training iterations  $T$ , Quantile  $p$ , Corruption Percentage  $\epsilon$ , Input Parameters  $d$ , Batch Size  $m$

**Output:** Trained Parameters,  $\theta$

**Data:** Inliers:  $y|x \sim \mathcal{N}(x^2 - x + 2, 0.01)$ , Outliers:  $y|x \sim \mathcal{N}(-x^2 + x + 4, 0.01)$

```

1:  $\theta_1 \leftarrow \mathcal{N}(0, \sigma)^d$ 
2: for  $k \in 1, 2, \dots, T$  do
3:    $I \subseteq [n]$  of size  $m$ 
4:    $\nu = (X_I \theta_k - y_I)^2$ 
5:    $\hat{\nu} = \text{sorted}(\nu)$ 
6:    $t_{k+1} = \hat{\nu}_{mp}$ 
7:    $t_{k+1} = \frac{1}{mp} \sum_{i=1}^{mp} \nu_i$ 
8:    $L := \sum_{i=1}^{mp} \mathbf{x}_i^\top \mathbf{x}_i$ 
9:    $\alpha := \frac{1}{2L}$ 
10:   $\theta_{k+1} = \theta_k - \alpha \nabla_{\theta_k} g(t_{k+1}, \theta_k)$ 
11: end
12: return  $\theta_T$ 

```

---

## E PROOFS FOR CONVERGENCE

### E.1 PROOF OF LEMMA 4.6

*Proof.* We will investigate the two cases  $t_{k+1} \leq t$  and  $t_{k+1} > t_k$ .

**Case (i)**  $t_{k+1} \leq t_k$

Let us first expand out  $g(t_k, \theta_k)$  with the knowledge that  $t_k \geq \hat{\nu}_k$

$$g(t_k, \theta_k) = t_k - \frac{1}{np} \sum_{i=1}^n (t_k - \nu_i)^+ \quad (76)$$

$$= t_k - \frac{1}{np} (np)t_k + \frac{1}{np} \sum_{i=1}^{np} \nu_i + \frac{1}{np} \sum_{i=np}^n (t_k - \nu_i)^+ \quad (77)$$

$$= \frac{1}{np} \sum_{i=1}^{np} \nu_i + \frac{1}{np} \sum_{i=np}^n (t_k - \nu_i)^+ \quad (78)$$

$$g(t_{k+1}, \theta_k) - g(t_k, \theta_k) = \frac{1}{np} \sum_{i=1}^{np} \nu_i - \left( \frac{1}{np} \sum_{i=1}^{np} \nu_i + \frac{1}{np} \sum_{i=np}^n (t_k - \nu_i)^+ \right) \quad (79)$$

$$= -\frac{1}{np} \sum_{i=np}^n (t_k - \nu_i)^+ \quad (80)$$

**Case (ii)**  $t_{k+1} > t_k$

Since we know  $t_k$  is less than  $\nu_{np}$ , WLOG we will say  $t_k$  is greater than the lowest  $n(p-\delta)$  elements, where  $\delta \in (0, p)$ .

$$g(t_k, \theta_k) = t_k - \frac{1}{np} \sum_{i=1}^n (t_k - \nu_i)^+ \quad (81)$$

$$= t_k - \frac{1}{np} \sum_{i=1}^{n(p-\delta)} (t_k - \nu_i)^+ \quad (82)$$

$$= t_k - \frac{1}{np} (n(p-\delta))t_k + \frac{1}{np} \sum_{i=1}^{n(p-\delta)} \nu_i \quad (83)$$

$$g(t_k, \theta_{k+1}) - g(t_k, \theta_k) = \frac{1}{np} \sum_{i=1}^{np} \nu_i - \left( \delta t_k + \frac{1}{np} \sum_{i=1}^{n(p-\delta)} \nu_i \right) \quad (84)$$

$$= \left( \frac{1}{np} \sum_{i=n(p-\delta)}^n \nu_i \right) - \delta t_k \quad (85)$$

This concludes the proof.  $\square$

## F CONVERGENCE ANALYSIS

### F.1 PROOF OF THEOREM 3

*Proof.*

**Assumption 3.** Let us assume the errors of  $\theta_k$  are normally distributed with respect to  $\mathbb{P}$  and  $\mathbb{Q}$ .

By Assumptions 1 and 2 we can do the following manipulations:

**Math can be condensed I think**

$$\begin{aligned}
\mathbb{E} [\|\theta^\top P - y_P\|_2^2] &= \mathbb{E} [\|\theta^\top P\|_2^2 - 2\theta^\top P y_P + y_P^\top y_P] \\
&= \mathbb{E} [(\theta^\top P)^\top (\theta^\top P)] - 2\mathbb{E} [\theta^\top P y_P] + \mathbb{E} [y_P^\top y_P] \\
&= \mathbb{E} [P^\top \theta \theta^\top P] - 2\mathbb{E} [\theta^\top P (\beta_P^\top P)] + \sum_{i=1}^{np} \mathbb{E} [y_{iP}^2] \\
&= \mathbb{E} [P^\top \theta \theta^\top P] - 2\mathbb{E} [\theta^\top P (\beta_P^\top P)] + \sum_{i=1}^{np} \text{Var} (\beta_P^\top P_i) + \mathbb{E} [\beta_P^\top P_i]^2 \\
&= \mathbb{E} [P^\top \theta \theta^\top P] - 2\theta^\top \mathbb{E} [P (\beta_P^\top P)] + \sum_{i=1}^{np} \text{Var} (\beta_P^\top P_i) + \mathbb{E} [\beta_P^\top P_i]^2 \\
&= \sum_{i=1}^{np} (\theta^\top p_i)^2 - 2\theta^\top \mathbb{E} [P (\beta_P^\top P)] + np (\epsilon_P + y_P^2) \\
&= \sum_{i=1}^{np} (\theta^\top p_i)^2 - 2\theta^\top \mathbb{E} [P (\beta_P^\top P)] + np (\epsilon_P + y_P^2) \\
&= \sum_{i=1}^{np} (\theta^\top p_i)^2 - 2np \theta^\top p y_P^2 + np (\epsilon_P + y_P) \\
&= np ((\theta^\top p)^2 - 2\theta^\top p y_P + y_P^2 + \epsilon_P) \\
&= np ((\theta^\top p)^2 - 2\theta^\top p \beta_P^\top p + (\beta_P^\top p)^2 + \epsilon_P) \\
&= np ((\theta^\top \beta_P) - (\beta_P^\top p))^2 + np \epsilon_P \\
&= np ((\theta - \beta_P)^\top p)^2 + np \epsilon_P
\end{aligned}$$

This result is accurate as it shows when  $\theta = \beta_P$  the expectation is equal to the variance in  $\beta_P$ .

$$\begin{aligned}
\mathbb{E} [\|\beta_P^\top P - y_P\|_2^2] &= np ((\beta_P^\top p)^2 - 2(\beta_P^\top p)(\beta_P^\top p) + (\beta_P^\top p)^2 + \epsilon_P) \\
&= np \epsilon_P
\end{aligned}$$

Therefore we can similarly say,

$$\mathbb{E} [\|\beta_Q^\top P - y_Q\|_2^2] = np ((\theta - \beta_Q)^\top q)^2 + np \epsilon_Q \quad (86)$$

By assumption 3 we assume normal error, thus we are now interested in calculating the variance.

The first few steps will follow straight from our result on Expectation.

$$\begin{aligned}
\text{Var} (\|\theta^\top P - y_P\|_2^2) &= \text{Var} (\|\theta^\top P\|_2^2 - 2\theta^\top P y_P + y_P^\top y_P) \\
&= \text{Var} ((\theta^\top P)^\top (\theta^\top P)) - 2\text{Var} (\theta^\top P y_P) + \text{Var} (y_P^\top y_P)
\end{aligned}$$

Now that we have the Expected Value and Variance of Squared Error we now want to calculate the expected number of points in the  $p$  sub-quantile. This is equivalent to:

$$n(1 - \varepsilon) \mathbb{P} [P \leq Q_p] \quad (87)$$

So we must calculate the quantity  $Q_p$ , which is also  $t$ .  $\square$

## F.2 PROOF OF THEOREM 4

*Proof.* Note Assumption 2 tells us the whole distribution is sampled from the same distribution. Let us define two functions for the empirical loss on  $\mathbb{P}$  and  $\mathbb{Q}$

$$\phi(\theta) = \frac{1}{np} \sum_{i=1}^m (\theta^\top \mathbf{p}_i - y_i)^2 \quad (88)$$

$$\psi(\theta) = \frac{1}{np} \sum_{i=1}^l (\theta^\top \mathbf{q}_i - y_i)^2 \quad (89)$$

These two functions hold nice properties.

$$\nabla_{\theta} \phi(\theta) = \frac{1}{np} \sum_{i=1}^m 2\mathbf{p}_i (\theta^\top \mathbf{p}_i - y_i) \quad (90)$$

$$\nabla_{\theta} \psi(\theta) = \frac{1}{np} \sum_{i=1}^l 2\mathbf{q}_i (\theta^\top \mathbf{q}_i - y_i) \quad (91)$$

Here we note that the summation of these derivatives is equal to the theta update

$$\nabla_{\theta_k} g(t_{k+1}, \theta_k) = \nabla_{\theta_k} \phi(\theta) + \nabla_{\theta_k} \psi(\theta) \quad (92)$$

$$\mathbb{E} [\nabla_{\theta} \phi(\theta)] = \frac{1}{np} \sum_{i=1}^{np(1-\epsilon)} 2\mathbb{E} [\mathbf{p}_i] \mathbb{E} [\theta^\top \mathbf{p}_i - y_i] \quad (93)$$

$$= \frac{1}{np} \sum_{i=1}^{np(1-\epsilon)} 2\mathbb{E} [\mathbf{p}_i] \mathbb{E} [(\theta^\top - \beta_P^\top) \mathbf{p}_i] \quad (94)$$

$$= \frac{2}{np} \sum_{i=1}^{np(1-\epsilon)} \mu (\theta^\top - \beta_P^\top) \mu \quad (95)$$

$$= 2(1-\epsilon) \mu \mu^\top (\theta - \beta_P) \quad (96)$$

We will use similar logic to find the Expectation of the derivative w.r.t  $\mathbb{Q}$

$$\mathbb{E} [\nabla_{\theta} \psi(\theta)] = 2\epsilon \mu \mu^\top (\theta - \beta_Q) \quad (97)$$

Thus we can calculate the expected derivative

$$\mathbb{E} [\nabla_{\theta} g(t_{k+1}, \theta_k)] = \mathbb{E} [\nabla_{\theta} \phi(\theta_k)] + \mathbb{E} [\nabla_{\theta} \psi(\theta_k)] \quad (98)$$

$$= 2(1-\epsilon) \mu \mu^\top (\theta - \beta_P) + 2\epsilon \mu \mu^\top (\theta_k - \beta_Q) \quad (99)$$

$$= 2\mu \mu^\top (\theta_k - (1-\epsilon)\beta_P - \epsilon\beta_Q) \quad (100)$$

Let us now calculate the expected change in  $\theta$  in each iteration. We will start with the  $\theta$ -update as described in Equation 11.

$$\mathbb{E} [\theta_{k+1}^\top] = \theta_k^\top - \frac{1}{2L} \mathbb{E} [\nabla_{\theta} g(t_{k+1}, \theta_k)] \quad (101)$$

We can now use the expected derivative in equation 100

$$= \theta_k^\top - \frac{1}{2L} (2\mu \mu^\top (\theta_k - (1-\epsilon)\beta_P - \epsilon\beta_Q)) \quad (102)$$

$$= \theta_k^\top - \frac{1}{L} (\mu \mu^\top (\theta_k - (1-\epsilon)\beta_P - \epsilon\beta_Q)) \quad (103)$$

$$= \left( \mathbf{I} - \frac{1}{L} \mu \mu^\top \right) \theta_k^\top + \frac{1-\epsilon}{L} \mu \mu^\top \beta_P + \frac{\epsilon}{L} \mu \mu^\top \beta_Q \quad (104)$$

Let us now calculate  $\mathbb{E}[\theta_{k+1}\mu]$

$$\mathbb{E}[\theta_{k+1}^\top \mu] = \left( \left( \mathbf{I} - \frac{1}{L} \mu \mu^\top \right) \theta_k + \frac{1-\varepsilon}{L} \mu \mu^\top \beta_P + \frac{\varepsilon}{L} \mu \mu^\top \beta_Q \right)^\top \mu \quad (105)$$

$$= \left( \theta_k^\top \left( \mathbf{I} - \frac{1}{L} \mu \mu^\top \right) + \frac{1-\varepsilon}{L} \beta_P^\top \mu \mu^\top + \frac{\varepsilon}{L} \beta_Q^\top \mu \mu^\top \right) \mu \quad (106)$$

$$= \left( \theta_k^\top \mu - \frac{1}{L} \theta_k^\top \mu \mu^\top \mu + \frac{1-\varepsilon}{L} \beta_P^\top \mu \mu^\top \mu + \frac{\varepsilon}{L} \beta_Q^\top \mu \mu^\top \mu \right) \quad (107)$$

Note  $\mathbb{E}[\mu^\top \mu] = \text{Var}[\mu] + \mu^2 = C$  for simplicity

$$= \theta_k^\top \mu - \frac{C}{L} \theta_k^\top \mu + \frac{C(1-\varepsilon)}{L} \beta_P^\top \mu + \frac{C\varepsilon}{L} \beta_Q^\top \mu \quad (108)$$

$$\theta_{k+1}^\top \mu - \theta_k^\top \mu = \left( -\frac{C}{L} \theta_k^\top + \frac{C(1-\varepsilon)}{L} \beta_P^\top + \frac{C\varepsilon}{L} \beta_Q^\top \right) \mu \quad (109)$$

It thus follows nicely

$$\theta_{k+1} - \theta_k = -\frac{C}{L} \theta_k + \frac{C(1-\varepsilon)}{L} \beta_P + \frac{C\varepsilon}{L} \beta_Q \quad (110)$$

This gives us insight into how  $\theta_{k+1}$  changes. We can now calculate a telescopic sum to see the change in  $\theta$  after  $T$  iterations. We will first assume  $\varepsilon$  does not change. Furthermore, let us note we start at  $\theta_0 = \mathbf{0}$ . Let us display a couple of iterations to show how  $\theta_k$  changes

$$\theta_0 = \mathbf{0} \quad (111)$$

$$\theta_1 = \frac{C(1-\varepsilon)}{L} \beta_P + \frac{C\varepsilon}{L} \beta_Q \quad (112)$$

$$\theta_2 = -\frac{C}{L} \left( \frac{C(1-\varepsilon)}{L} \beta_P + \frac{C\varepsilon}{L} \beta_Q \right) + \frac{C(1-\varepsilon)}{L} \beta_P + \frac{C\varepsilon}{L} \beta_Q \quad (113)$$

$$= \frac{CL(1-\varepsilon)}{L^2} \beta_P + \frac{CL\varepsilon}{L^2} \beta_Q - \frac{C^2(1-\varepsilon)}{L^2} \beta_P - \frac{C^2\varepsilon}{L^2} \beta_Q \quad (114)$$

$$= \frac{(CL - C^2)(1-\varepsilon)}{L^2} \beta_P + \frac{(CL - C^2)\varepsilon}{L^2} \beta_Q \quad (115)$$

This only converges to  $\beta_P$  when  $\varepsilon$  is decreasing. Otherwise it will simply converge to the OLS optimal solution we proved in Theorem 1.

We are thus interested in  $\mathbb{P}[\varepsilon \rightarrow 0]$ . The fact that  $\theta_0 = \mathbf{0}$  is vital to the convergence analysis. Furthermore, the coefficients of  $\beta_P$  and  $\beta_Q$  are also important for this analysis. This is why for the first iteration, it is vital not to randomize  $\theta_0$ , but to randomize the first  $np$  elements trained on. As initial  $\theta_0$  is deterministic of the final distribution.

**Definition 8.** A function  $f$  is  $L$  smooth if

$$\|f(x) - f(y)\| \leq L \|x - y\| \quad \forall x, y$$

We will now find the expected change in loss with respect to the distributions of  $\mathbb{P}$  and  $\mathbb{Q}$  in each iteration. Furthermore, let us note  $g(t, \theta)$  is  $L$ -smooth with respect to  $\theta$ . Thus we can use the properties of Definition 8.

$$\mathbb{E}[g(t_{k+1}, \theta_{k+1})] \leq \mathbb{E}[g(t, \theta_k)] + \langle \nabla_\theta \mathbb{E}[g(t_k, \theta_k)], \theta_{k+1} - \theta_k \rangle + \frac{L}{2} \|\theta_{k+1} - \theta_k\|_2^2 \quad (116)$$

$$= \mathbb{E}[g(t, \theta_k)] + \langle \nabla_\theta \phi(\theta) + \nabla_\theta \psi(\theta), \theta_{k+1} - \theta_k \rangle + \frac{L}{2} \|\theta_{k+1} - \theta_k\|_2^2 \quad (117)$$

We can use the  $\theta$  update rule described in Equation 11

$$\begin{aligned} &= \mathbb{E}[g(t, \theta_k)] + \langle \nabla_\theta \phi(\theta) + \nabla_\theta \psi(\theta), -\frac{1}{L} (\nabla_\theta \phi(\theta_k) + \nabla_\theta \psi(\theta_k)) \rangle \\ &\quad + \frac{L}{2} \|\phi(\theta) + \nabla_\theta \psi(\theta)\|_2^2 \end{aligned} \quad (118)$$

We can now use the expected derivative described in Equation 100

$$\begin{aligned}
&= \mathbb{E}[g(t, \boldsymbol{\theta}_k)] + \langle 2\boldsymbol{\mu}\boldsymbol{\mu}^\top (\boldsymbol{\theta}^\top - (1 - \epsilon)\boldsymbol{\beta}_P^\top - \epsilon\boldsymbol{\beta}_Q^\top), -\frac{1}{L}2\boldsymbol{\mu}\boldsymbol{\mu}^\top (\boldsymbol{\theta}^\top - (1 - \epsilon)\boldsymbol{\beta}_P^\top - \epsilon\boldsymbol{\beta}_Q^\top) \rangle \\
&\quad + \frac{1}{2L} (2\boldsymbol{\mu}\boldsymbol{\mu}^\top (\boldsymbol{\theta}^\top - (1 - \epsilon)\boldsymbol{\beta}_P^\top - \epsilon\boldsymbol{\beta}_Q^\top))^\top (2\boldsymbol{\mu}\boldsymbol{\mu}^\top (\boldsymbol{\theta}^\top - (1 - \epsilon)\boldsymbol{\beta}_P^\top - \epsilon\boldsymbol{\beta}_Q^\top)) \\
&\hspace{25em} (119)
\end{aligned}$$

$$\begin{aligned}
&= \mathbb{E}[g(t, \boldsymbol{\theta}_k)] - \frac{1}{2L} (2\boldsymbol{\mu}\boldsymbol{\mu}^\top (\boldsymbol{\theta}^\top - (1 - \epsilon)\boldsymbol{\beta}_P^\top - \epsilon\boldsymbol{\beta}_Q^\top))^\top (2\boldsymbol{\mu}\boldsymbol{\mu}^\top (\boldsymbol{\theta}^\top - (1 - \epsilon)\boldsymbol{\beta}_P^\top - \epsilon\boldsymbol{\beta}_Q^\top)) \\
&\hspace{25em} (120)
\end{aligned}$$

$$(121)$$

## G ADDITIONAL EXPERIMENTS

Figure 3: Quadratic Regression  $n = 1000$  and  $\epsilon = 0.2$

## H EXPERIMENTAL DETAILS

### H.1 STRUCTURED LINEAR REGRESSION DATASET

We will describe  $\mathbb{P}$  and  $\mathbb{Q}$  in the Linear Regression Dataset.

$$\mathbf{x} \sim \mathcal{N}(0, 4)^{500}$$

$$\mathbf{m} \sim \mathcal{N}(0, 4)^{500}$$

$$b \sim \mathcal{N}(0, 4)$$

$$\mathbf{m}' \sim \mathcal{N}(4, 4)^{500}$$

$$b' \sim \mathcal{N}(4, 4)$$

$$n_{\text{train}} = 2\text{e}3$$

$$\mathbb{P} : y|\mathbf{x} \sim \mathcal{N}(\mathbf{m}^\top \mathbf{x} + b, 0.1)$$

$$\mathbb{Q} : y|\mathbf{x} \sim \mathcal{N}(\mathbf{m}'^\top \mathbf{x} + b', 0.1)$$

Please note  $\mathbf{m}$ ,  $b$ ,  $\mathbf{m}'$ ,  $b'$ , are all sampled independently.

### H.2 NOISY LINEAR REGRESSION DATASET

We will describe  $\mathbb{P}$  and  $\mathbb{Q}$  in the Linear Regression Dataset.

$$\mathbf{x} \sim \mathcal{N}(0, 4)^{500}$$

$$\mathbf{m} \sim \mathcal{N}(0, 4)^{500}$$

$$b \sim \mathcal{N}(0, 4)$$

$$\mathbf{m}' \sim \mathcal{N}(4, 4)^{500}$$

$$b' \sim \mathcal{N}(4, 4)$$

$$n_{\text{train}} = 2\text{e}3$$

$$\mathbb{P} : y|\mathbf{x} \sim \mathcal{N}(\mathbf{m}^\top \mathbf{x} + b, 0.1)$$

$$\mathbb{Q} : y|\mathbf{x} \sim \mathcal{N}(\mathbf{m}'^\top \mathbf{x} + b', 0.1)$$

Please note  $\mathbf{m}$ ,  $b$ ,  $\mathbf{m}'$ ,  $b'$ , are all sampled independently.

### H.3 QUADRATIC REGRESSION DATASET

We will describe  $\mathbb{P}$  and  $\mathbb{Q}$  in the Quadratic Regression dataset.

$$x \sim \mathcal{N}(0, 1)$$

$$n_{\text{train}} = 10\text{e}4$$

$$\mathbb{P} : y|x \sim \mathcal{N}(x^2 - x + 2, 0.01)$$

$$\mathbb{Q} : y|x \sim \mathcal{N}(-x^2 + x + 4, 0.01)$$

### H.4 DRUG DISCOVERY DATASET

This dataset is downloaded from Diakonikolas et al. (2019). We utilize the same noise procedure as in Li et al. (2020).

$\mathbb{P}$  is given from an 80/20 train test split from the dataset.

$\mathbb{Q}$  is random noise sampled from  $\mathcal{N}(5, 5)$ .

The noise represents a noisy worker

### H.5 BASELINE METHODS IN SECTION 5

Here we will describe the objective functions used in the synthetic data experiments.

**Ordinary Least Squares (OLS)** can be solved utilizing the Moore Penrose Inverse.

$$\mathbf{X}^* = (\mathbf{X}^\top \mathbf{X})^{-1} \mathbf{X}^\top \mathbf{y} \quad (122)$$

**Huber Regression** is solved with the following objective function.

$$L_\delta(y, f(\mathbf{x})) = \begin{cases} \frac{1}{2}(y - f(\mathbf{x}))^2 \\ \delta \cdot (|y - f(\mathbf{x})| - \frac{1}{2}\delta) & \text{otherwise} \end{cases} \quad (123)$$

**RANSAC**
